

Practical 4 – Spring Boot

Objective

- In this practical, you will create a simple Spring Boot web application that allows users to submit **Product** information either via an HTML form or through URL parameters.
- The application will then display the submitted information on a single response page that triggers a JavaScript alert showing the product details.

Getting Started

- Create a Spring Boot project named P7_knum (replace knum with your knumber)
- Includes the “Spring Reactive Web” and “Thymeleaf” dependencies.

Tasks

1. Create the model

- For the model, create a Product class.
- This class should contain the following fields:
 - productName (String)
 - productPrice (Double)
 - quantity (Integer)
- Include:
 - A no argument constructor
 - A parameterized constructor
 - Getter and setter methods

2. Create the controller

- Your controller should handle:
 - GET requests to “/”
 - Displays the HTML form for submitting product details
 - POST requests to “/submit”
 - Handles form submission and sends the product details to the display view page
 - GET requests to “/url”
 - Accepts product details as URL parameters and sends them to the display view page

3. Create the views

a) Form view (form.html)

- Displays an HTML form that allows users to enter:
 - Product Name
 - Product Price
 - Quantity
- The form should submit data to /submit using the **POST** method.

b) Display view (display.html)

- Displays the same data received from either the form or the URL.
- Include a JavaScript alert that shows the values of productName, productPrice, and quantity.

Testing

Once your application is running, test both submission methods:

- Using the form:
 - <http://localhost:8080>
- Using URL parameters:
 - <http://localhost:8080/url?productName=Laptop&productPrice=999.99&quantity=2>
